

Climate scientists misinform about global warming!

The climate scientists refer to measurements of extremely high temperatures and claim that the increase is accelerating,

Measurements of global temperature over the past 45 years show the following: The temperature is rising linearly. That is there is no accelerating temperature rise! According to the trend in the measurements, the temperature rises by only 0.015 - 0,021 C/year.

There is no extreme increase in global temperature!

The measurements also show peaks in the measurements from time to time. Then we also experience occurrences of extra extreme weather. They are not permanent and therefore do not represent climate change. Climate variations is the correct term for what we experience. These variations cannot be attributed to variations in the atmosphere, its content is actually very stable.

There is no extreme global warming going on!
